

QUESTION

Putting into consideration a market vender, with examples, discuss the concept of functions

Definition: it is a self-contained reusable block of code designed to perform a specific task. so think of it as setting up a market workflow and once you figure out exactly to do the task you package it up so you can repeat it instantly anytime you need it

The function def: a programming statement that creates a reusable block of code

- We use the def keyword to build the function and give it a name

Vendor concept: setting up a specific stall for a specific job, like making a fresh cup of coffee or deep-frying samosas you set up once, then stock up and wait

Parameters and arguments(inputs)

inputs are called arguments (the actual values provided)

parameters are the place holders in the function that catch the function

Vendor concept: a customer walks up and orders coffee, but they want it with milk and 3 spoons of sugar. The customer details are the inputs

The body logic

The indented line of code under or within the def statement that processes you're input

Vendor concept: the actual steps you take when making the coffee like brew the coffee pour in milk the add sugar

Return statement: it sends the calculated result back to whoever asked for it

Vendor concept: handing the finished cup of coffee to the customer

A Simple Example

Here is how you would translate a simple "Sell Matooke" (green bananas) or "Calculate Profit" transaction into a Python function

def

calculate daily profit (sales revenue, total expenses):

```
# This is the function body
```

```
profit = sales revenue – total expenses
```

```
return profit
```

```
# Calling the function to sell at different stalls
```

```
Market stall A = calculate daily profit (50000, 20000)
```

```
Market stall B = calculate daily profit (75000, 30000)
```

```
print (f" Stall A profit: {market stall A}")
```

```
print (f" Stall B profit: {market stall B}")
```

```
def staff ():
```

```
    num1, num2 = 10, 20
```

```
    print(num1 + num2)
```

```
    num1, num2 = 100, 200
```

```
    print(num1 + num2)
```

```
staff()
```
